Listening to nature's voice: invasive species, Earth jurisprudence and compassionate conservation

Sophie Riley

Senior Lecturer, University of Technology Sydney

Humanity's land management practices reconstruct nature by destroying and degrading habitats, species and ecosystems, and creating environmental imbalance. The latter can manifest in overabundant or invasive species, imposing a welfare burden on unwanted animals when they are targeted for eradication and control. Such approaches not only overlook animal wellbeing, but also ignore the role that humans have played in species' classifications. As societies grapple to manage the unstable environments they have created, they have also started to realize that standards set by paradigms, such as sustainable development, do not sufficiently engage with the efficacy or ethics of existing practices. This article argues that a synthesis of law and science, drawn respectively from emerging paradigms, such as the Great Law of Earth jurisprudence and principles of compassionate conservation, can help guide environmental regimes towards more effective and ethical outcomes. From a legal perspective, the Great Law subordinates human law to a metaphorical nature's voice, while from a scientific perspective the scientific underpinnings of compassionate conservation identify that voice. Although compassionate conservation injects empathy into the decision-making processes, it is a form of empathy based on science that commences from the stipulation that regulators should first do no harm. It is a call that is specifically relevant to invasive species, where current regulation is based on harming certain species, while simultaneously overlooking environmental threats generated by humans. By using science to identify nature's voice, and law to listen to that voice, regulators can start to design regimes that work with nature, rather than trying to reconstruct and dominate it.

Keywords: *Earth jurisprudence, rights of Mother Earth, compassionate conservation, invasive species*

1 INTRODUCTION

Writing in 2013, Marc Bekoff described how humanity's land management practices have 'redecorated' nature by destroying and degrading habitats, species and ecosystems.¹ These practices include land clearing as well as the control and eradication of wild animals and the management of overabundant species, pest species, invasive or

1. Marc Bekoff in Marc Bekoff (ed), *Ignoring Nature No More: The Case for Compassionate Conservation* (The University of Chicago Press, 2013) Preface, xiii, xix.

invasive alien species (hereafter, collectively referred to as ‘invasive species’).² Such practices have been criticized for their ‘subjective and anthropocentric nature’, where killing unwanted species becomes the norm and ‘humane treatment is often the first casualty’.³

Some commentators have critiqued these approaches for their lack of moral probity and tendencies towards domination of nature, trajectories that have not been averted by sustainable development, the predominant environmental paradigm.⁴ Yet, ethical insufficiency and domination of nature were far from key aims of sustainable development, which in its inception was constrained by socio-economic and environmental considerations. These were reflected in a vision of biodiversity protection based on intrinsic value, which was articulated in the preamble to the Convention on Biological Diversity, 1992 (CBD).⁵ This would have attributed value to biodiversity, irrespective of human needs, potentially containing anthropocentric ideals within broad moral parameters.⁶

At the same time, intrinsic value does not suggest that all parts of nature or biodiversity are created equal, or indeed, are equally valued. The CBD, for example, tacitly acknowledges that different categories of biodiversity warrant different levels of protection. Threatened species and degraded ecosystems merit special protection,⁷ while invasive alien species (IAS), those introduced species that threaten biodiversity, need to be eradicated and controlled.⁸ Furthermore, ascribing intrinsic value to species does not identify the locus of value, which could occur at the individual, population, species or ecosystem levels. It is an important issue, which determines the emphasis of regimes and whether administrators pay regard to animals in collectives, or as individuals.

The CBD categorises wildlife in collectives, at the species and population levels, implying that value is also located in the collective.⁹ As a general principle, this can be problematic in the design and implementation of environmental regimes for two

reasons: first, it does not sufficiently incorporate individual animal wellbeing; and, second, by focusing on species in the collective, it makes it easier to avoid difficult questions associated with human impacts on the environment. However, as with critiques of sustainable development, society has started to question the efficacy and ethics of these approaches.¹⁰ One part of the debate examines whether sustainable development is, itself, sufficiently robust to deal with ethical considerations.¹¹ Another part examines whether emerging concepts, such as Earth jurisprudence and compassionate conservation, can provide frameworks for designing environmental regimes with greater efficacy and ethical integrity.¹²

The purpose of this article is to evaluate Earth jurisprudence and compassionate conservation, through the lens of invasive species regulation, in order to identify regulatory weaknesses and suggest improvements in the management of these species. Although the study focuses on invasive species, the analysis and general conclusions potentially apply to human–nature interactions at large. Invasive species have been selected for discussion because their regulation is ostensibly based on utilitarian balancing designed to protect biodiversity. Yet, in reality, regulation is frequently an attempt to deal with unsustainable land management practices.¹³ It is argued that this places an unanswered welfare burden on invasive species which are targeted for eradication and control, while far-reaching human activities, such as vegetation clearance and habitat destruction, mostly continue unchecked.¹⁴ In order to make the material manageable, the discussion focuses on Australia; however, the problems faced by Australia are analogous to problems in other jurisdictions, meaning that much of the discussion would also be relevant in these cases.¹⁵

The article commences by examining the problem of invasive species and their regulation in the context of sustainable development. It then moves to an evaluation

of the significance of Earth jurisprudence and compassionate conservation with their calls respectively, in a metaphorical sense, to listen to ‘nature’s voice’ and ‘do no harm’.¹⁶ Part of the analysis involves reviewing provisions in the CBD and the Guiding Principles for the Prevention, Introduction and Mitigation of Impacts of Alien Species that Threaten Ecosystems, Habitats or Species (Guiding Principles) for their ethical consistency.¹⁷ Although the Guiding Principles note that measures should be ‘environmentally benign’ and ‘ethically acceptable’ to stakeholders,¹⁸ these initiatives fall short of the scientific and ethical dimensions that underpin Earth jurisprudence and compassionate conservation.¹⁹ It is concluded that society needs a fresh approach where humans take responsibility for their ‘re-decoration’ of nature by designing and implementing holistic regimes that are consistent with principles drawn and synthesized from Earth jurisprudence and compassionate conservation.

2 THE PROBLEM OF INVASIVE SPECIES AND THEIR REGULATION

The CBD uses the phrase ‘invasive alien species’ to describe species that have been ‘introduced outside [their] ... natural past or present distribution’ and which ‘threaten biological diversity’.²⁰ Biodiversity protection is also part of the rubric of sustainable development, and accordingly Article 8(h) of the CBD provides that States are under obligation to prevent the entry of invasive alien species, as well as eradicate and control them. Sustainable development itself is defined as development that does not compromise the ability of future generations to meet their own needs.²¹ In recognition of the fact that development can lead to the introduction of invasive species, and undermine objectives of sustainability, the Guiding Principles identify links between development and invasive species, including, trade, transportation, tourism and the effects of climate change.²² Deliberate and accidental introductions, for example, frequently occur as a result of inadequate identification, evaluation and management of

environmental risks in the trade of ornamental plants, aquarium pets, cut flowers and pasture grasses.²³ What is more, human activities relating to agriculture, and resource management, can create ecosystem imbalance, contributing to invasiveness or overabundance of alien, as well as, native species.²⁴

Much has been written on the impacts of invasive species, from threats to biodiversity to economic consequences in agricultural systems.²⁵ The CBD concludes that:

[i]nvasive alien species have invaded and affected native biota in almost every ecosystem type on Earth, and have affected all major taxonomic groups. In economic terms, the costs of invasive alien species are significant. Total annual costs, including losses to crops, pastures and forests, as well as environmental damages and control costs, have been conservatively estimated to be in the hundreds of billions of dollars and possibly more than one trillion. This does not include valuation of species' extinctions, losses in biodiversity, ecosystem services and aesthetics.²⁶

For these reasons, the CBD obliges States to manage invasive alien species. Significantly, it is the categorisation of species as invasive, rather than alien, which acts as the trigger for measures. This is a clear consequence of obligations deriving from Article 8(h) that are based on alien species that threaten ecosystems, habitats or other species. As already noted, Article 8(h) is also supplemented by the Guiding Principles that detail how to make the Article operational. They initiate a twofold focus, starting with preventing introductions across international boundaries, and

then implementing mitigation measures, by way of eradication and control, at the national level.²⁷ This means that regulators need to make decisions identifying environmental threats and also the types of measures required to manage those threats. Against this backdrop, justification for eradication and control reaches beyond the ambit of Article 8(h) to include killing overabundant native species in order to ensure survival of their populations, as well as killing native and introduced species to prevent their interfering with human activities.²⁸

Underpinning these decisions, lie value choices concerning what is worthy of protection. If it is kept in mind that not all biodiversity is protected to the same extent, and that some species will be earmarked for eradication, this raises a number of ethical issues that are not adequately addressed within the CBD. In particular, these developments cast doubt on whether regimes are 'ethically acceptable' to stakeholders and are 'environmentally benign', two concepts mentioned in the Guiding Principles as relevant to invasive species' regimes.²⁹

In Australia, regulation comprises a mix of legislation, guidelines, management plans and codes of conduct. This includes declaring a species a pest,³⁰ listing the impacts of animals as a threatening process and/or the implementation of management plans to reduce populations below a threshold considered harmful.³¹ What is more, management invariably comprises lethal methods.³² At first glance, regimes appear comprehensive, but in reality, they can engender priorities which focus on reducing numbers of species, rather than dealing with the underlying reasons why species become invasive.³³ This not only raises ethical considerations inherent in choosing lethal measures, but it also means that regimes may not be effective in

27. Guiding Principle 4, for example promotes the Ecosystem Approach, focussing on international obligations to minimize introductions across international boundaries, while Guiding Principles; Guiding Principle 15 focusses on reducing numbers of IAS, as well as the damage caused by them.

the long term.³⁴ To be effective requires extending the regulatory focus away from individual species and towards human–wildlife interactions in order to manage the causes, rather than the symptoms of invasiveness. To do otherwise shifts the accountability burden towards wildlife and away from human activities that destroy habitat, fragment forests and degrade biodiversity.³⁵

Urbanisation is a case in point. At present, approximately one-half of the world's population live in urban areas and it is anticipated that this will increase to '70 per cent by 2050'.³⁶ When humans gravitate towards urban areas, forests and vegetation are cleared for development and sometimes re-vegetated, upsetting the original mix of species. Particularly profound changes occur with reduction of density and variety of avian species because clearing fosters colonization by large birds and introduced species and the depletion of small native birds.³⁷ In Australia, these tendencies are exacerbated by re-planting with popular native cultivars such as bottle brushes and grevilleas and/or feeding native birds which may also encourage populations of larger, aggressive birds.³⁸ In such cases, bird numbers do not 'explode' but respond to increased availability of resources, and similarly, bird numbers will abate in response to limiting resources.³⁹ The most common birds found after clearing and re-planting are rock doves and rainbow lorikeets and in areas at the periphery of cleared sites, noisy miners and crows.⁴⁰ The converse has also been observed, so that non-cleared areas support a higher number of birds, as well as higher numbers of koalas, possums and gliders.⁴¹

Disturbed landscapes can also act as a source for colonizing surrounding areas and can alter connectivity of landscapes and ecosystems by enabling or hindering the migration of species.⁴² In addition, changing the mix of vegetation can alter species

interactions, making degraded ecosystems more susceptible to invasion.⁴³ This, in fact, is precisely what has occurred in the case of overabundant bell miners in New South Wales. Land management practices have created habitat that not only promotes the establishment of bell miners, but also supports increased numbers of psyllids, a small insect that feeds on tree sap and is implicated in eucalyptus die-back.⁴⁴ In a flow-on effect, habitat which favours bell miners will preclude other insect-eating birds, further increasing numbers of psyllids and accelerating eucalyptus die-back.⁴⁵ Similar problems have occurred in the case of overabundant noisy miners, where clearing low-lying shrubs favours increased populations of these birds, leading to the decline of smaller birds, such as wrens.⁴⁶

In an attempt to manage excess bell miners and noisy miners, authorities have used environmental legislation to list their overabundance as a threatening process.⁴⁷ This acts as tacit acceptance that the presence of these birds results in significant ecological disturbance which must be mitigated by eradication and control measures. However, research demonstrates that combinations of human-induced events are likely to have greater detrimental impacts on ecosystems.⁴⁸ In the case of eucalyptus die-back for example, land clearing and fragmentation, logging, fire and grazing regimes, weed management, pathogens and hydrological factors are more important agents of environmental degradation than abundance of bell miners.⁴⁹

From an ethical perspective, the philosophy which guides invasive species regimes is based on utilitarianism, a form of consequentialism that judges the morality of actions by their outcomes. The killing of noisy miners and bell miners is, therefore, justified where it results in increased populations of small birds, or reduction in eucalyptus die-back, as long as certain safeguards are employed that, as far as possible, take into account the welfare of noisy miners and bell miners. Yet, regulators avoid grappling with human-induced degradation, while simultaneously seeing solutions in terms of killing species that have taken advantage of the environment created by humans.⁵⁰ It is also an approach that does not adequately take into account the individual welfare burden placed on targeted species, a standpoint that is closely aligned to control and domination of nature.⁵¹

Similar arguments apply to other areas, such as agricultural regions. In Australia, rangelands extend across 75 percent of the country and have been significantly altered by livestock grazing.⁵² This has led to clashes among stakeholders resulting in the killing of an array of animals, including, kangaroos, wombats, dingoes and cockatoos, in order to safeguard agriculture and livestock production.⁵³ Consequently, regulators have started relaxing the need for specific licences to kill birds, including cockatoos and magpies, as well as promoting commercial hunting, by way of 'consumptive use', for animals such as kangaroos.⁵⁴ In some cases, the latter has been economically successful, but if used as a conservation tool it raises issues similar to those raised by management of noisy miners and bell miners: more specifically, whether eradication and control represent attempts to remedy ineffective land management.⁵⁵ In addition, the wellbeing of targeted animals invariably receives insufficient attention.⁵⁶ By way of illustration, the debate surrounding commercial harvesting of kangaroos indicates that regulators have considered the effectiveness of the regime itself, but have not adequately dealt with welfare considerations.⁵⁷

Approaches which evince insufficient regard for ethical concerns can lead to public disengagement and hostility, potentially undermining regimes. Lack of ethical engagement and public opposition, for example, have been identified as significant reasons for controversy surrounding eradication programmes, such as horse culling in Mount Kosciuszko national park in Australia.⁵⁸ This is perhaps not surprising as horse culls involve aerial shooting, with questionable welfare outcomes, of an animal immortalised in Australian culture.⁵⁹ Given the unpopularity of this proposal, protests by members of the Australian public led to the abandonment of aerial horse culls and then to the protection of wild horses for cultural reasons.⁶⁰ These matters can be

viewed on several levels, from a failure of animal welfare systems, to the wider perspective of humanity's discordant relationship with the environment. At their core, however, they provide examples that justify calls for new approaches.

3 NEW APPROACHES: EARTH JURISPRUDENCE AND COMPASSIONATE CONSERVATION

Two emerging approaches, Earth jurisprudence based on legal precepts and compassionate conservation based on science, are particularly relevant in the management of invasive species. They provide complementary approaches, which contribute essential elements to reconfiguring society's interactions with nature.

3.1 Earth jurisprudence and the Great Law

Earth jurisprudence draws on the work of Thomas Berry, who was a Catholic priest and environmentalist. The catalyst for Berry's views was condemnation of economic and anthropocentric ideals, which Berry regarded as a pernicious influence that would invariably lead to environmental degradation.⁶¹ Berry, therefore, called for new perspectives, set out in his book the *Great Work: Our Way into the Future* (the Great Work), which would transform humanity's relationship with the Earth from one of exploitation to one that is 'mutually beneficent'.⁶² A cornerstone of the Great Work derives from Berry's arguments that humans comprise only one part of Earth's community and accordingly do not sit at the apex of an Earth hierarchy.⁶³ Rather, all living and non-living entities have vital and interdependent roles to play.⁶⁴

Berry's philosophies have been adopted within concepts such as wild law, and find their most detailed expression in the notion of Earth jurisprudence.⁶⁵ Although assigning a definition to Earth jurisprudence is as elusive as pinning down the concept of jurisprudence itself, Filgueira and Mason describe Earth jurisprudence as 'the philosophy of law and regulation that gives formal recognition to the reciprocal relationship between humans and the rest of nature'.⁶⁶ This definition captures the essence

Sydney Moring Herald (11 June 2017) available from www.smh.com.au/environment/brumbies-cull-battle-over-wild-horses-in-kosciusko-national-park-heats-up-20170609-gwnyob.html, accessed 18 March 2019; for attitudes on horse culling generally, Dale G Nimmo, Kelly K Miller and Robyn Adams, 'Managing Feral Horses in Victoria: A Study of Community Attitudes and Perceptions' (2007) 8(3) *Ecological Management and Restoration* 237, 239–40; Kosciusko Wild Horse Heritage Act 2018 (NSW), s 4 states that the object of the legislation is to 'recognise the heritage value of sustainable wild horse populations within parts of Kosciuszko National Park and to protect that heritage'.

of Berry's views, which, as just indicated, are based on the interconnectedness of life on Earth and moral obligations in that regard.⁶⁷ It is an outlook that stands in contrast to human law that is grounded in anthropocentrism and positivism, where social mores and ethical probity barely rate a mention.⁶⁸

In accordance with Berry's views, Earth jurisprudence subordinates human law to the authority of the 'Great Law' (also referred to as the Great Jurisprudence).⁶⁹ The Great Law and human law thus sit in a hierarchical relationship where human law depends on the Great Law and also needs to be consistent with it.⁷⁰ Yet, the content of the Great Law is not settled. For some, the universe and the laws of nature can be seen as a source of the Great Law because the universe determines key criteria upon which all life depends, such as, 'time scales, life spans, seasons and temperature ranges'.⁷¹ For others, however, references to the 'laws of nature' are too broad and vague to form the basis of policy and regulation.⁷² Burdon describes the Great Law as representing 'the rules or principles of nature, which are discoverable by human beings and relevant to human-earth interaction'.⁷³ Accordingly, the Great Law would comprise key ecological principles that remain central and constant, such as the interconnectedness of the web of life.⁷⁴ Determining what these principles are, and their relative importance to law and policy, requires drawing science and law together, an issue discussed further in part four of this article.

Although the content of the Great Law is still evolving, Earth jurisprudence has been elaborated in terms of 'rights' of the Earth community, which supersede human law:

- The Earth community and all the beings that constitute it have fundamental 'rights', including the right to exist, to inhabit or a place to be, and to participate in the evolution of the Earth community.
- The rights of each being are limited by the rights of other beings to the extent necessary to maintain the integrity, balance and health of the communities within which it exists.
- Human acts or laws that infringe these fundamental rights violate the fundamental relationships and principles that constitute the earth community ('the Great Jurisprudence') and are consequently illegitimate and 'unlawful'.
- Humans must adapt their legal, political, economic and social systems to be consistent with the Great Jurisprudence and to guide humans to live in accordance with it, which means that human governance systems at all times take account of the interests of the whole Earth community and must...
- recognise all members of the Earth community as subjects before the law, with the right to the protection of the law and to an effective remedy for human acts that violate their fundamental rights.⁷⁵

These rights are designed to allow life on Earth to exist and fulfil its evolutionary role,⁷⁶ but are also ‘role-specific or species-specific’, attaching in different ways to different entities and Earth components.⁷⁷ Hence, the rights of trees would be specific to trees and would also differ from the rights of rivers, which again would be different from the rights of birds and the rights of mammals.⁷⁸ One common feature, however, is that these rights originate from the very existence of entities or components, rather than from rights conferred by humans.⁷⁹

As with Earth jurisprudence itself, the scope, ambit and content of these rights are still developing. From one perspective the use of rights terminology represents a means of making Berry’s ideals operational, and indeed Berry himself spoke of rights.⁸⁰ However, Berry did not fully embrace the legal and policy standpoints inherent in a jurisprudential approach. He had particular reservations concerning the use of legal rights language where it was devoid of ethical considerations, fearing it might not be the best way of promoting the Great Work.⁸¹ In addition, while he theoretically saw the law as an instrument of positive change, he also saw it as an instrument of complicity, capable of maintaining an unjustifiable status quo.⁸² Nevertheless, Berry was sufficiently realistic to concede that legal rights represented the most feasible way forward. He ultimately regarded law and morality as being interwoven, potentially allowing each to compensate for the other’s weaknesses.⁸³

One open question concerns the locus of rights proffered by Earth jurisprudence, whether this lies at the collective or individual level. This is an important issue, particularly in the regulation of invasive species, because the welfare of these species needs to be considered at an individual level.⁸⁴ Earth jurisprudence clearly envisages that collectives have rights, consisting of rights to participate in the Earth community and to evolve. Individual rights comprise rights that ‘all members’ of the Earth community have to seek redress for ‘human acts that violate their fundamental rights’.⁸⁵ At the same time, individual rights ‘are limited by the rights of other beings to the extent necessary to maintain the integrity’ of the Earth community. These provisions are similar to Articles found in the Universal Declaration of Rights of Mother Earth, adopted at the World People’s Conference on Climate Change and the Rights of Mother Earth, held in Cochabamba 2010 (Universal Declaration).⁸⁶

Article 2(3) of the Universal Declaration provides that animals have individual rights against torture or cruel treatment by humans; while Article 1(7) states that the 'rights of each being are limited by the rights of other beings and any conflict between their rights must be resolved in a way that maintains the integrity, balance and health of Mother Earth'. The rights afforded under Article 2(3) are, therefore, analogous to provisions in Earth jurisprudence that proscribe 'human acts that violate' other's rights. Although Earth jurisprudence does not specifically identify that individual animals are a beneficiary of this proscription, it also does not exclude individuals from this sphere of rights. However, given that both the Universal Declaration and Earth jurisprudence limit the rights of beings and entities by the rights of other beings and entities, the application of these principles to individual animals seems akin to animal welfare provisions found in national jurisdictions that proscribe cruel treatment, unnecessary harm and suffering.⁸⁷

If in fact this is the case, one difficulty deriving from the 'rights' language used by the Universal Declaration and Earth jurisprudence, stems from the weak design and application of national welfare regulation, which is frequently attenuated by qualifications as to what is necessary, unnecessary or acceptable.⁸⁸ Such qualifications can, and do, lead to poor welfare outcomes.⁸⁹ Moreover, although Article 1 of the Universal Declaration is drafted in 'rights' language, it also diminishes the power of individual rights by providing that the rights of Mother Earth override other rights. This is justified on the basis that animals and other living beings are an indivisible and interrelated part of Mother Earth.⁹⁰ In this respect, Article 1 is very similar to key tenets of Earth jurisprudence that focus on the interconnectedness and integrity of life on Earth, and leave the issue of individual versus collective rights, very much open to debate.

Maloney and Cashford argue that if entities such as species and populations enjoy rights, then this extends to individuals because species and populations consist of individuals.⁹¹ Burdon has similarly argued that because Earth jurisprudence recognizes the intrinsic value of nature, law should impose obligations on humans that enable the rights of 'every being ... to be recognized and revered'.⁹²

Yet, others question whether Earth jurisprudence can extend this far.⁹³ It is not, therefore, clear how Earth jurisprudence would manage the interplay between rights and welfare. If rights were to accrue only to the collective, this is analogous to the approach taken by sustainable development, which also locates value in the collective.

93. *Ibid.*

Consistent with that position, it is difficult to see what true rights animals would have, as opposed to welfare obligations that target human behaviour. Moreover, given that the Great Law subordinates human law, the relationship among differing rights per se, the value of the collective and the value of the individual will need to be refined and settled. At present, human law with respect to individual animals is based on welfare, a utilitarian balancing that is subject to many qualifications, which are not necessarily consistent with the Great Law.⁹⁴ This is an unsettled area that will undoubtedly receive further attention as the concept of Earth jurisprudence evolves and develops.

At the same time, the fact that Earth jurisprudence discourse is framed in legal terminology does not mean that solutions are delineated by legal precepts. Science, for example, is vital to resolving environmental problems, including those that raise legal and ethical issues. Science can provide details on the nature of environmental problems and the consequences of interventions. More specifically, it can detect nature's voice, and thus help identify the content of the Great Law.

3.2 Compassionate conservation

Compassionate conservation evolved out of concern that conservation efforts frequently involve an 'entanglement of harm and care',⁹⁵ normalizing views that conservation necessitates harming some animals, in order to save others, or, killing animals to protect the environment at large.⁹⁶ This may include killing individuals from one species to protect another species, or killing individuals within the same species to protect the collective.⁹⁷

Compassionate conservation challenges these approaches, instead calling for regimes to be based on 'empathy ... for nonhuman animals'.⁹⁸ As indicated in the introduction to this article, empathy in this instance is based on science, not emotion. At the same time, it is a version of science that takes individuals into account, while being guided by broad ethical principles.⁹⁹ Ramp and Bekoff argue that:

[u]nlike the dominant utilitarian approach to conservation, which puts the cost of reaching conservation targets squarely on the shoulders of other animals, a compassionate ethic for conservation brings empathy into decision-making alongside other values. It is not a rights position but, rather, puts forward a scientific and evidence-based conceptual approach that stipulates that conservation initiatives should first do no harm.¹⁰⁰

In similarity with Earth jurisprudence, compassionate conservation challenges society's anthropocentrism and the exploitative model of human-nature domination.¹⁰¹ Unlike Earth jurisprudence, this challenge does not lead to legal interests or legal rights, but to a science-based decision-making paradigm that starts from

94. White (n 88) 391–93; generally, Dalle (n 88); Sherley (n 88) 454; Thiriet (n 88) 163–65, 180–84.

the premise that regulation 'should first do no harm'. This stands in direct contrast to current management approaches, based on sustainable development, which have been criticized for becoming almost synonymous with continual growth and the commodification of nature.¹⁰²

For these reasons, at least one commentator has examined whether sustainable development should be paraphrased as 'living sustainably' and incorporate an ethical dimension, that 'reinvent[s] virtue ethics] ... for contemporary life'.¹⁰³ Virtue ethics is a philosophy drawn from the writings of Aristotle and focuses on the morality of people's behaviour.¹⁰⁴ As a starting point, Aristotle rejected the notion that animals were worthy of direct moral concern, because they lacked rationality.¹⁰⁵ Yet, Aristotle's philosophies on virtue and teleology are still relevant, combining personal integrity with the notion that entities have value beyond their use to humans.¹⁰⁶ Empathy, which is a core component of compassionate conservation, derives from these concepts. In an ecological setting, science identifies the purpose of ecosystems, populations and individual entities, as well as the capacity of collectives and individuals within ecosystems to flourish.¹⁰⁷ Ethics, and more particularly virtue ethics, identifies human qualities, or virtues, which, in a regulatory context, allow entities and collectives to flourish and fulfil their purpose.¹⁰⁸ Of necessity, this should cause humans to reconsider behaviour and activities, such as land clearing, that elevate human wants at the expense of the environment, including collectives, and/or individual entities.

By focusing on human behaviour, virtue ethics represents a radical departure from current ideals, based on utilitarianism, that target the consequences of an action. The latter has invariably allowed regulators to justify killing animals 'for the greater good if it results in a larger balance of benefits over the detriment of killing'.¹⁰⁹ As a practical example, utilitarianism justifies killing overabundant noisy miners, bell miners, cockatoos and wombats because it is regarded as an appropriate response to the threats presented by these animals. By way of contrast, virtue ethics impels humans to examine the necessity of killing, the method of killing, whether killing is an effective response, and whether other forms of regulation are feasible and appropriate. It should lead regulators to examine why noisy miners, bell miners, cockatoos and wombats have become invasive and modify human behaviour accordingly. The exhortation from compassionate conservation to 'do no harm' is not merely a call to consider whether the consequences of an action can be justified, but a call to consider how human activities contribute to harm and how to obviate that harm, including at an individual level.

By questioning the welfare burden placed on individual animals, compassionate conservation implicitly critiques the fixation on collectives. Yet, collectives have been the traditional focus of science; hence, to make compassionate conservation

workable, science also needs to start considering individuals.¹¹⁰ To do otherwise not only restricts scientific knowledge and understanding, but also has ethical consequences, because it strengthens the traditional focus on collectives.¹¹¹ At the same time, compassionate conservation does not authorize regulators to ignore ecosystem health, or allow the welfare of individual entities to override other considerations, but it does mean that meaningful regard for individual entities needs to be taken into account as part of management practices.¹¹²

The discussion should not be taken as a conclusion that Earth jurisprudence and compassionate conservation are consistent in every respect. Notwithstanding the metaphorical call to 'listen to nature's voice', determining the practical ambit of Earth jurisprudence and its relationship to science still remains somewhat elusive. Science-based approaches focus on causative factors and outcomes while Earth jurisprudence also admits moral consideration of the relationship between humans and nature. This potentially creates a tension, not only between scientific and ethical interpretations of the Great Law itself, but also between Earth jurisprudence and compassionate conservation.

Nevertheless philosophies of virtue ethics can draw together the science-based precepts of compassionate conservation and the ethical underpinnings of the Great Law, by acknowledging the need to modify human behaviour, both in its ethical foundations and its practical import.¹¹³ The differences between compassionate conservation and Earth jurisprudence lie in the method chosen to achieve these objectives, with compassionate conservation being science-based and Earth jurisprudence being legally-based. These differences, however, do not signify that the two approaches are incompatible. Indeed, Earth jurisprudence and compassionate conservation potentially provide a way to synthesize science, law and ethics, commensurate with Berry's hopes that law and ethics would draw upon the other's strengths and compensate for the other's weaknesses.¹¹⁴

4 REDESIGNING REGIMES: INVASIVE SPECIES, EARTH JURISPRUDENCE AND COMPASSIONATE CONSERVATION

From the discussion thus far, the regulation of invasive species raises many contentious issues, including how regulators perceive environmental harm, the individual versus collective debate and the welfare burden placed on invasive species. Although regulators frequently frame the solution in terms of classifying species as invasive and concentrating efforts on eradication and control, these approaches can be counter-productive because they do not address the heart of the problem, which is how regulators deal with humans and their conflicting views on environmental management.

Conflict may be perceived in terms of human-nature interactions, or in terms of human-human interactions.¹¹⁵ Environmental problems, for example, are often disagreements about divergent outlooks on land management practice, engendering a plurality of stakeholders and voices. Lunney points out that humanity has an ethical

imperative not to 'let our native fauna slide to extinction ... [and to] manage overabundant populations'.¹¹⁶ However, while some property holders may see invasive species as a resource; others might regard these species as the cause of environmental degradation; yet again, others might see invasive animals as a symptom of human-created environmental problems and argue that regulation needs to pay more attention to individual animal wellbeing.¹¹⁷ These differing outlooks alter how the problem, and thus the solution, is perceived; where the focus centres on species and their classifications it side-steps the significance of the human element. If the problem, however, were to be recalibrated as a human problem, it becomes clearer that the solution lies in modifying human behaviour, or more specifically, ensuring that human law is consistent with the Great law.

In pondering how this could occur, Cullinan notes that society would need to 'refine its ideas about what is "right" and "wrong"'.¹¹⁸ In particular, law and policy based on Earth jurisprudence should draw regimes towards a form of governance that emphasizes 'mutually-beneficial relations' among the Earth community.¹¹⁹ Human laws would therefore need to 'listen ... to nature'.¹²⁰ As already indicated, this requires input from science, yet such input alone does not resolve the issue, for science needs to be translated into law and policy. The latter, however, are mired by legal positivism, which traditionally attributes worth to humans and human ideals, isolating regimes from engagement with ethical precepts.¹²¹ It is at this point, that the Great Law, positioned above human law, can be critical to re-considering the reach of legal positivism, guiding human-nature interactions along more ethical pathways.

In the context of invasive species, this should involve evaluating why species become invasive and, rather than automatically killing animals which have taken advantage of altered environments, listening to the needs of nature in order to redress ecosystem imbalance. Some of the most profound changes would be seen in the classification, and thus treatment, of individual animals and the way regulators conceptualize environmental threats; matters that are also important to the call from compassionate conservation to do no harm.

This exercise does not start from a blank slate. Filgueira and Mason, for example, have surveyed a range of laws applying to mountains, forests and endangered species and have identified regulation that is already commensurate with key tenets of Earth jurisprudence, such as, the interdependency of life.¹²² In an analogous way, Australian policy instruments relevant to invasive species' regulation, broach ethical considerations and refer to the need for holistic regimes where eradication and control measures

are part of broader strategies.¹²³ However, as with the laws examined by Filgueira and Mason, objectives in Australian instruments are not supported by targets and performance indicators, hindering laws and strategies from becoming fully operational.¹²⁴ Animal welfare standards are a case in point. Strategies such as the Animal Biosecurity and Welfare Strategic Plan 2013–15 contain broad aspirational statements dealing with animal welfare.¹²⁵ Yet, there is little elaboration as to what this means in practice and how it will be achieved. As a stark illustration, control of foxes in NSW still depends on sodium fluoroacetate (*1080*), which is promoted as being humane, notwithstanding the fact that its use remains contentious.¹²⁶

Indeed, the use of lethal methods is particularly controversial and represents an area of invasive species regulation where compassionate conservation can be helpful. Primarily, its scientific underpinnings can identify problems and outcomes across a range of measures, setting limits on use of lethal control.¹²⁷ Commentators have already turned their minds to this question, devising critical safeguards for regimes.¹²⁸ Mellor and Littin, for example, provide that, at the very least, regulators need to be satisfied that interventions are necessary and justifiable and have also examined whether non-lethal methods are available.¹²⁹ Others note that lethal control requires a high threshold of justification that takes into account the lives and wellbeing of both target and non-target animals.¹³⁰ Moreover the justification for lethal measures

must be supported by strong environmental criteria which make it feasible that interventions will reverse environmental harm.¹³¹ Finally, it almost goes without saying that regulators need to choose the most humane methods and if no such methods are available, they should devise alternative processes.¹³²

In the case of overabundant birds, such as noisy miners and bell birds, 'doing no harm' would question utilitarian approaches that justify killing where benefits elsewhere are said to outweigh the harm to noisy miners and bell miners. Moreover, an Earth jurisprudence approach, relying on scientific evidence to find nature's voice, would question wholesale killing and instead, consider long-term solutions such as prohibiting clearing of low-lying vegetation, forbidding destruction of canopy cover, encouraging re-vegetation and undertaking selective weed removal.

From a practical point of view, eradication and control are also less likely to be successful than measures implemented to prevent degradation of ecosystems in the first place; they are also likely to be less successful than measures undertaken to restore ecosystems that take into account habitat and resource preferences of individual species, particularly those at risk, or those that are starting to become invasive.¹³³ However, preventing ecosystem degradation frequently involves prohibiting or strictly controlling land clearance, something that in Australia is very contentious.¹³⁴ The question of what amounts to appropriate restoration of ecosystems could also prove challenging as it focusses on providing habitat and resources for an array of species, rather than promoting popular cultivars.¹³⁵ To be effective these approaches entail multifaceted solutions, that of necessity require uniting landholders, nursery vendors and other stakeholders.¹³⁶ They also require a strong knowledge-base and continual scrutiny of the effectiveness of regimes, underpinned by 'clearly defined objectives ... monitoring and audit procedures', perspectives that are not always found in environmental regulation.¹³⁷

In truth, governments have been criticized for their frequent focus on short-term, 'crisis' measures, which do not provide long-term solutions to what, effectively,

are chronic problems.¹³⁸ This not only leads to lack of long-term reduction in population numbers of invasive species, but also side-steps engagement with the theoretical and ethical foundations of humanity's relationship with the environment.¹³⁹ However, while humans have the potential to dominate ecosystems, they also have the capacity to design ethical regimes.¹⁴⁰ The commonalities that weave through the suggestions for reform rest on how management decisions are made and the moral probity of regimes, dilemmas that place humans at the forefront. Earth jurisprudence and compassionate conservation provide a means of incorporating these considerations into decision-making.

5 CONCLUSION

Sustainable development, the predominant environmental decision-making paradigm, identifies links between invasive species and threats to biodiversity that, in accordance with utilitarian philosophies, call for eradication and control of invasive species. At the same time, control and eradication raise practical and ethical considerations that are unevenly addressed by current regulation.¹⁴¹ In particular, authorities rarely question why lethal methods are a first response, and why the role of humans in encouraging species to become invasive is often overlooked. These regulatory gaps are indicative of humanity's inattentiveness to environmental problems it has created, leading to discordant relationships with the Earth and its ecological systems. For these reasons, Earth jurisprudence and compassionate conservation emphasize that humans need to start listening to nature. From a legal perspective this entails paying more than lip service to the interdependent relationship of humans with the Earth and ensuring that human laws are consistent with the Great Law of Earth jurisprudence. Although, for some, the Great Law derives from the universe itself; for others it is reflected, more pragmatically, in accepted and broadly-based scientific principles. These principles will continuously be developed and refined; however, the cornerstone lies in accepting the interconnectedness of life on Earth and the fact that humans are only one element in this web. Regulators, therefore, need to take heed of scientific knowledge, including those parts that critique current approaches, and use it to underpin the Great Law.

Indeed, ideals flowing from Earth jurisprudence and compassionate conservation tacitly acknowledge that society cannot resolve environmental problems with the same techniques and pathways that created those problems. Instead of attempting to redecorate and dominate nature, society needs to work with nature, aligning law and policy with nature's laws. Accordingly, humans need to modify their own behaviour and engage with frameworks presented by emerging paradigms such as Earth jurisprudence and compassionate conservation that place humans at the forefront of resolving environmental problems.
